1 Introduction

This technical note summarises the spreadsheet-based modelling work carried out to identify at a high-level the indicative traffic flow changes anticipated on the highway network based on new development proposals being examined as part of the local plan.

Mott MacDonald (MM) has been commissioned by Southend-on-Sea Borough Council (SBC) to provide support in respect of the preparation of the Transport Evidence for their emerging Local Plan.

As part of this work MM has produced a spreadsheet analysis tool to assist with this exercise, the specification of which has been discussed in detail with officers of SBC as well as Rochford District Council (RDC) and Essex County Council (ECC). The approach followed, which uses a high-level spreadsheet tool, represents an appropriate and agreed analysis for this stage of the Local Plan process and it is acknowledged that more detailed analyses would need to be undertaken at a later stage based on strategic or operational modelling. The Southend Multi-Modal Model (SoSMMM) is being further developed and is therefore expected to help contribute to this further work, in due course.

Following this introduction, the remainder of the report is structured as follows:

- Chapter 2 of this technical note details the spreadsheet-based modelling approach and its purpose.
- Chapter 3 outlines the model set-up whilst Chapter 4 outlines the forecasting approach and assumptions incorporated for the Do Minimum model.
- Chapter 5 outlines the options tested as defined by Southend Borough Council to align with their
 emerging local plan and presents the results for each option. It also includes details of the predicted
 flow level change compared to the Do Minimum for each option at the key junctions included in the
 model.
- Chapter 6 summarises the findings and presents any key limitations, where relevant, at this stage.

2 Approach

2.1 Purpose

This technical note has been prepared by Mott MacDonald (MM) on behalf of Southend Borough Council (SBC) as part of the preparation of Transport Evidence for their emerging Local Plan.

The intention is to illustrate the potential impact of development allocations proposed by SBC within the Local Plan on the transport network. The main focus was given to the highway network at a junction level but potential changes on other modes and the environment are also outlined.

A spreadsheet model has been developed using MS Excel to provide an initial analysis tool. This technical note outlines the methodology used and assumptions made to develop the spreadsheet modelling tool to help identify at a high-level the likely areas of traffic flow changes on the highway network under different development assumptions, which may lead to transport issues in the SBC area. It has been agreed that this approach represents an appropriate and proportionate method at this stage of the Local Plan process and the associated limitations are presented, where appropriate, recognising that further work will be required in due course. In particular, this is expected to likely include strategic or operational modelling at a later stage and in this regard it is recognised that the SoSMMM is currently being updated.

The model area also includes the Rochford District Council area and the process of the spreadsheet model tool development incorporated inputs for both local authority areas. Although the focus of this report is Southend, commentary therefore includes the adjacent Rochford area, where appropriate.

2.2 Study Area and Junction Choice

Several criteria were considered when selecting the junctions to be included in the spreadsheet model tool. These can be summarised as follows:

- Reliable and recent turning count data availability;
- Junctions that are key to connecting the area in a wider context; and
- Major junctions of interest along the modelled corridors for Southend and Rochford
 - either because they carry high levels of traffic at present
 - or are anticipated to be significantly impacted by future developments

The final study area was discussed in detail with SBC, RDC as well as ECC, prior to the assessment work being undertaken.

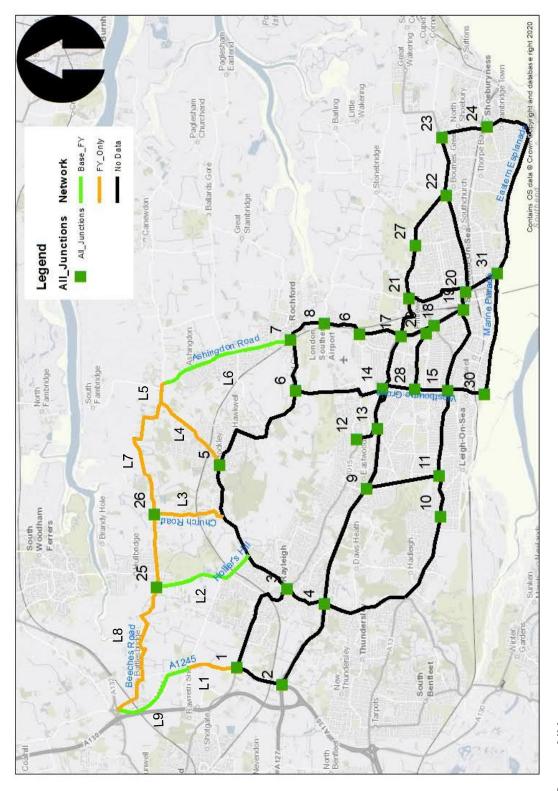

Figure 2.1 shows the network considered in the spreadsheet model, covering both Southend and Rochford, while a list of the junctions and their method of control are shown in Table 2.1.

It is apparent that the majority of junctions in Southend are either close to development clusters or important access junctions towards the two arterial roads, namely the A127 and A13. In the Rochford area, due to the limited availability of junction turning data, several connecting roads have been included to help supplement the network. This ensures that the best possible coverage is included in the assessment. For those shown in orange no base data was available and only full forecast development generated traffic volumes can be calculated within the spreadsheet model tool instead of the percentage increases.

Table 2.1: Spreadsheet model junctions

3 Base Model

3.1 Data Sources

The primary source of count data used for the spreadsheet base model tool aligns with the data collected for the development of the Southend-on-Sea Multi Modal Model (SoSMMM) with the majority of turning counts being the Manual Classified Turning Count (MCTC) counts. Of the 28 junctions with turning data, 24 are from SoSMMM. These were all collected between March and October 2018. Using data from such a consistent source ensures an enhanced model set-up and provides greater assurance for forecasting.

However, to ensure the spreadsheet model area had good model coverage, a further four sites were used, these were sourced from ECC's 'dolphins' database, which is the Essex wide traffic data collection site. These were turning counts collected between March and October during 2017.

Although there were few turning counts available within the Rochford area, base model data was available for three links including Hollier's Hill, A1245, and Ashingdon Road. These were incorporated into the model as they were included in the Better Queensway (BQ) strategic model and the forecast traffic distributions could be calculated.

3.2 Factors

As most of the data was collected in 2017 and 2018, growth factors derived from the Department for Transport (DfT) industry standard TEMPro database for both Southend-on-Sea and Rochford for the weekday AM and PM periods were used to create a consolidated 2019 base model. The average of the origin and destination factors was used consistently across all junctions.

Table 3.1 TEMPro growth factors

			AM			PM	
Level	Name	Origin	Destination	Average	Origin	Destination	Average
2017 - 2019	Rochford	1.0182	1.0253	1.0218	1.0220	1.0179	1.0200
	Southend-on-Sea	1.0229	1.0265	1.0247	1.0250	1.0226	1.0236
2018 - 2019	Rochford	1.0090	1.0125	1.0108	1.0110	1.0089	1.0100
	Southend-on-Sea	1.0113	1.0131	1.0122	1.0120	1.0112	1.0117

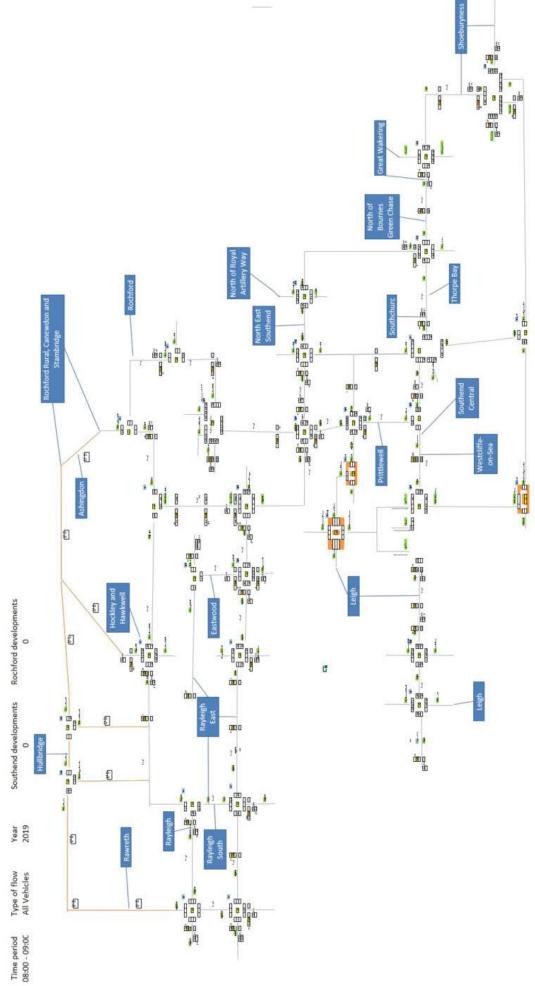

3.3 Model Set-up

The count data was processed and factored in tabular format and cumulated into one main dataset. In order to allow a better visual presentation, the stick-diagram network shown in Figure 3.1 was set up.

The values shown for each turning movement or link can be selected in a master tab allowing the selection of different time periods, vehicles or Passenger Car Units (PCUs) and different years via drop-down menus.

The network diagram also shows blue labels for cluster loading points that are used for adding forecast trips.

Figure 3.1 Illustration of spreadsheet model with cluster loading points

The cluster names are to illustrate the loading points onto the network. Many of the distances and directions of roads are distorted for the simplicity of the creation of the model and as such are not to scale.

4 Forecasting

4.1 Development assumptions

Development lists including Do Minimum and Do Something developments were provided by SBC and RDC, identifying those schemes with 'committed' status that should therefore be expected to be delivered during the Do Minimum scenario or come forward later, as part of the Local Plan proposals, through the Do Something scenario. The dwellings included in the modelling totalled 421 developments: 259 in Rochford and 162 in Southend. Varying levels of detail were provided for the developments and while the Rochford developments only include housing sites, Southend developments include housing and employment proposals.

In order to feed these details into the spreadsheet model consistently, further details were required. These included:

- Definition of Do Minimum (DM) and Do Something (DS) developments;
- Definition of forecast year (2028 or 2038);
- Clarification of development type for employment;
- Classification of development locations as Urban, Sub-urban or Rural; and
- Allocation to clusters.

The resultant set of assumptions were provided to SBC and RDC for their approval, prior to the completion of the assessment. In summary, the below were confirmed as part of this process.

Southend-on-Sea

- Developments include housing and commercial
- Developments that have had their planning permission granted are assumed to be committed and hence go into the DM model (26 developments), all others go into the DS.
- If a development is forecast to be delivered partially before 2028 with the residual after 2038, then the trips are split according to that proportion.
- Otherwise, the trips are split according to the information provided by Southend-on-Sea Borough Council

Rochford

- All developments are housing
- All DM developments are in the 2028 model as they are all scheduled to be built by financial year 2028-2029.
- For housing developments of more than 15 dwellings the assumption is that 35% of them will be affordable, otherwise it is assumed that none of them are affordable.
- The DS developments are split between 2028 and 2038 based on the information provided to us by Rochford District Council.

4.2 Trip Calculation

TRICS trip rates were derived to convert the development details into highway vehicle trip volumes. The rates used are shown below in Table 4.1 and Table 4.2. Destination trip rates represent the arrivals while origin rates are used to calculate the trips departing.

Table 4.1 Employment trip rates for vehicles (per 100sqm unless stated otherwise)

									•		
	A1	A2	A3	B1A	B1B	B1C	B8	C1 (Rooms)	D1	D2 (per ha)	Sui Generis (per ha)
AM destination	2.64	1.33		1.33	1.42	0.21	0.17	0.21	2.37	10.53	10.53
AM origin	2.30	0.15		0.15	0.16	0.05	0.05	0.32	1. 50	8.03	8.03
PM destination		0.12	0.40	0.12	0.12	0.05	0.04	0.24	0.34	29.98	29.98
PM origin		1.09	0.26	1.09	1.126	0.20	0.15	0.19	0.34	27.72	27.72

The majority of developments are proposed as residential dwellings.

The residential rates vary depending on location, with fewer trips typically generated in urban areas than in rural locations with less accessibility to alternative transport modes.

Affordable and private residential trip rates were extracted for mixed housing including houses and flats and are shown in Table 4.2.

Table 4.2 Residential Trip Rates by type of location (vehicle trips per dwelling)

			Reside	ntial - Priva	te		Residentia	l - Affordab	le
SBC/RDC defined areas	TRICS definition	AM Dest	AM Orig	PM Dest	PM Org	AM Dest	AM Orig	PM Dest	PM Org
Urban	Town Centre	0.025	0.200	0.250	0.075	0.063	0.102	0.074	0.063
Suburban	Edge of Town Centre and Suburban Area	0.124	0.349	0.341	0.199	0.144	0.229	0.300	0.229
Rural	Edge of Town	0.138	0.386	0.352	0.172	0.144	0.284	0.205	0.140

Although the rates for sub-urban and rural do not vary significantly it highlights car user trips are significantly higher in these areas when compared to developments in urban areas.

As mentioned, a series of development cluster locations were identified by SBC and RDC for the purposes of the assessment. The categorisation of each cluster to the different types of residential area were provided by SBC and RDC and summarised in Table 4.3

Table 4.3 Cluster to type of area

Cluster	Type of Area

D2	Leisure Centre 07_C					
Sui Generis	Leisure Centre 07_C					

4.3 Clusters

The development locations by cluster are shown in Figure 4.1.

Figure 4.1 Map of development and clusters

In the spreadsheet model the development trips are allocated to the model by cluster, rather than a more detailed zonal level. This means all development trips generated by different development sites within a cluster are generally loaded onto the modelled network at the same location. This is a simplification compared to strategic modelling but considered proportionate for this stage.

However, for some clusters with developments spread over a wider geographical area the clusters were broken down further, with loading locations applied on different sides of modelled junctions, where appropriate.

4.4 Distributions

For each cluster a trip distribution was selected from a zone in this area from the Southend Better Queensway (BQ) strategic SATURN model. These distributions were extracted for AM and PM, by origin and destination.

At the same time the census journey to work (JTW) data was extracted for the corresponding Middle Super Output Area (MSOA). Both distributions were compared to ensure they aligned well.

In some cases, manual adjustments were made to the strategic model distribution to improve the match to the JTW data.

Generally, the clusters stayed entirely within the boundaries of Southend-on-Sea/Rochford; apart from for North East Southend. This cluster covers an area which would have development extending across both authorities. In order to model the assumed access locations in more detail the North East Southend area was therefore broken down into three areas: North East Southend, North of Bournes Green Chase and North of Royal Artillery Way.

4.5 Distribution Adjustments

The aligned distributions from the BQ model and JTW data allowed the proportions of flows to be calculated for each cluster at each turning movement in the model.

For some clusters, the equivalent BQ zone had no trips and there was no corresponding MSOA data, and so some clusters were combined. This is the case for the following clusters:

- Shoeburyness
- Great Wakering

Other clusters in the BQ model had insufficient trips travelling west representing a mismatch to the MSOA data. For example, in the BQ model the distribution for Hullbridge did not contain many trips towards the west or north. However, the JTW data showed a greater proportion of trips with destinations in those directions. Therefore, corresponding volumes of trips were added through junctions 1 and 2 to represent trips that will be present as a result of further developments in Hullbridge.

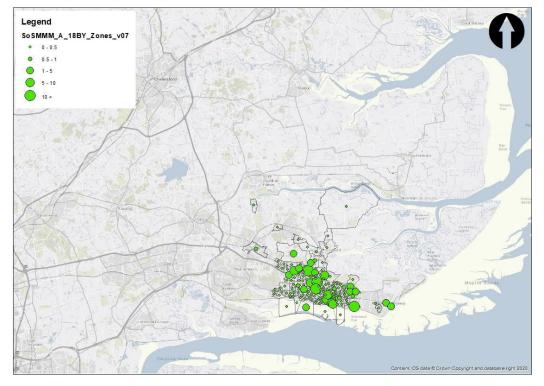

Figure 4.2 and Figure 4.3 show the example of the JTW and BQ model distributions for Hullbridge prior to the manual alignment.

Figure 4.2 : Commuting trips from Hullbridge AM (JTW data)

The JTW data shows commuting trips from Hullbridge have destinations across Southend and Rochford as well as further west and north.

Figure 4.3: Trips from Hullbridge AM (BQ model)

The zones in Figure 4.3: Trips from Hullbridge AM (BQ model) show the distribution from the strategic model, which was set up with focus on Better Queensway and hence did not include the trips to the west and north. This would have been outside of the Better Queensway study area.

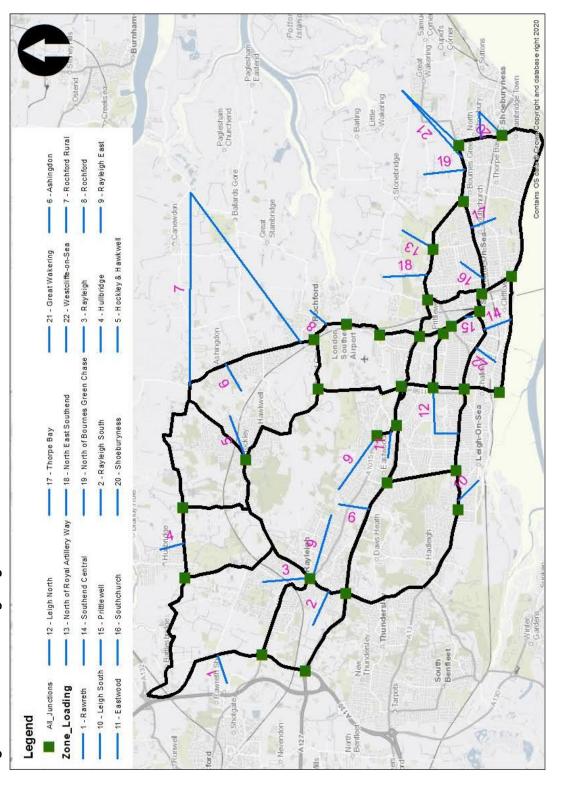

These manual adjustments for trips outside the model area were made to the following clusters:

- Hullbridge
- Rawreth
- Rayleigh (including Rayleigh south and Rayleigh East)

The following clusters were also manually adjusted to the BQ distributions to address issues where the zone with the most representative distribution would not have loaded onto the network at the cluster loading point:

- Hockley and Hawkwell
- Royal Artillery Way

Figure 4.4 Cluster Loading Diagram

4.6 Forecast Trips

For each cluster the calculated forecast trip volumes based on the selected developments were multiplied by the proportions defined by the distributions. This generated trips for all applicable junction turning movements.

For some junctions in the Rochford area, which are represented by external nodes in the BQ model, it was not possible to extract turning movements. Therefore, to establish the required proportions for the distributions the incoming and outgoing junction movements were used as an approximation. A similar approach was employed for large roundabouts modelled with separate nodes for each approach in the BQ model.

4.7 Dynamic TEMPro Factors

Although Do Minimum development details were provided by SBC and RDC it is vital to ensure that trip volumes for the Do Minimum align with TEMPro forecast levels to ensure a consistent comparison against the Do Something (with local plan developments) scenarios.

Base and future year trips were extracted using TEMPro v7.2. The Do Minimum total trip volume for Southend was then factored up to the future year TEMPro hourly trip volume for the AM and PM peaks. The same process was carried out for the Rochford area.

5 Development Options

5.1 Proposed Options

SBC provided three options for testing with the model. These represent different cluster combinations. A summary of the number of dwellings for each option and forecast year, as well as the number of employment sites, is shown in Table 5.1. These are considered additional to the developments specified for the Do Minimum and include windfalls.

Table 5.1 Summary of clusters provided by Southend-on-Sea Borough Council

		Option A			Option B			Option C	
Cluster	2028 dwellings	2038 dwellings	Com- mercial sites	2028 dwellings	2038 dwellings	Com- mercia I sites	2028 dwellings	2038 dwellings	Com- mercial sites
Eastwood	73	133	1	133	299	1	133	299	1
Leigh	435	801	17	435	807	17	435	807	17
North East Southend AoS	0	0	1	0	0	1	1,546	1,859	1
North of Royal Artillery Way	0	0	1	0	0	1	1,896	2,440	1
North of Bournes Green Chase	0	0	1	0	0	1	1,088	2,962	1
Prittlewell	941	1,071	3	1,192	1,555	3	1,192	1,555	3
Shoeburynes s	373	798	2	394	1,289	2	394	1,289	2
Southchurch	425	815	2	425	1,138	2	425	1,138	2
Southend (central)	3,214	4,874	18	3,334	5,659	18	3,334	5,659	18
Thorpe Bay	50	90	0	50	90	0	50	90	0
Westcliff-on- Sea	434	834	5	434	834	5	434	834	5
Total	5,945	9,416	49	6,397	11,671	49	10,927	18,932	49
% increase to previous option				7.6%	29.6%		70.8%	62.2%	

In order to model these options, factors were calculated based on the Do Minimum trip volumes to add the defined additional local plan volumes appropriately to the spreadsheet model. These factors were confirmed with SBC.

5.2 Result Analysis

5.2.1 Red – Amber – Green Indicator

In order to analyse the forecast results a Red – Amber – Green (RAG) indicator approach was used to identify the levels of trip increases compared to the Do Minimum at each junction or link represented in the spreadsheet model. An additional category was added resulting in the following set-up:

- 0%-5% Green
- 5%-10% Yellow
- 10%-20% Orange
- >20% Red

The trip volumes compared are for the total flows across all approaches at each junction rather than focusing on the average or worst performing turning movements. This means that for some junctions with only one particular approach showing a high flow level increase the overall junction flow level increase may show as less significant.

This output therefore provides a useful comparison across the study area, which can be viewed side-by-side for each of the options appraised. However, it is recommended that more detailed junction modelling is carried out for any junction showing a significant flow increase to ensure the junction operates well and liaison with officers and ECC should be utilised to help inform this process.

Additional to the figures showing categories of the percentile increase, a summary table is provided for each option showing the actual flow increase the RAG is based on. This enables a more detailed judgement to be formed about the significance of the potential impact. Table 5.2 summarises the flow levels for the base year and the 2038 Do Minimum. This shows a flow increase in a range between 200 and 900 trips per junction on average by 2038.

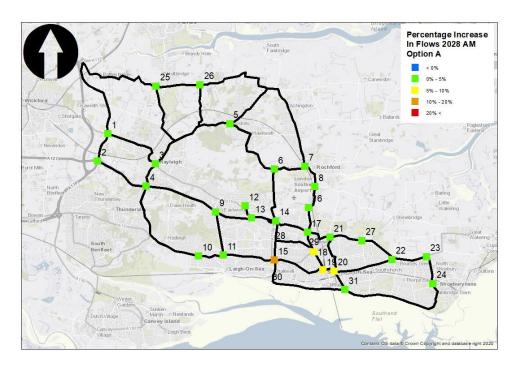

Table 5.2: Base and 2038 DM Flows

Junction	Base AM	Base PM	DM AM	DM PM	DM	DM
	Flow	Flow	Flow	Flow	minus	minus
1	2019 3,612	2019 3,907	2038 3,947	2038 4,260	Base AM 335	Base PN 353

5.3 Option A

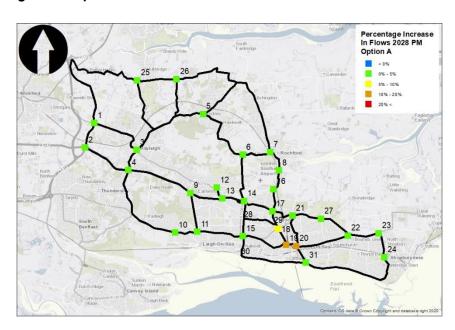

The results for Option A show that in 2028 the majority of junctions showing a significant increase compared to the Do Minimum are those located in the centre of Southend, Prittlewell and to the west at Jct 15 (A1158 Westbourne Grove / A13 London Rd). This is due to the large number of additional dwellings proposed in Southend central and the adjacent Prittlewell area generating about 900 additional origin trips in the AM peak. The remainder of additional trips do not increase the total junction trip levels by more than 5% compared to the DM as they are spread across the Southend area.

Figure 5.1: Option A 2028 AM

In the PM peak 2028 the proportionally greatest increase is forecast for junctions 19 and 20 (Queensway / A13 Roundabout / A1160) in the town centre with increases up to 20%. However, as in the AM peak the remainder of the junctions assessed show proportionally lower levels of increase.

Figure 5.2 Option A 2028 PM

Traffic flows based on Option A in 2038 show that in the AM and PM there are forecast to be increases of over 10% for most of the key junctions in Southend Central and Prittlewell. Jct 24 (A13 / Delaware Rd / Caulfield Rd / Elm Road) also shows a significant increase compared to the DM traffic volumes. Jct 15 (A1158 Westbourne Grove / A13 London Rd) shows an increase of over 20% in the AM peak. Further the junctions in and west of Rochford also show increases above 5% in both peak periods. These results align with the further increases in dwellings at Southend central, Shoeburyness and Southchurch over this second 10-year period. During the PM peak increases forecast are also significantly greater than for 2028 as similar trip volumes return to the new dwellings.

Figure 5.3 Option A 2038 AM

	Link9	1,776	1,862	1,854	1,955	-	3	-	6

Table 5.3 shows the additional flow at each link or junction compared to the Do Minimum scenario for 2028 and 2038.

The largest increase in flows are junctions 19 and 20 in central Southend.

5.4 Option B

Figure 5.5 Option B 2028 AM

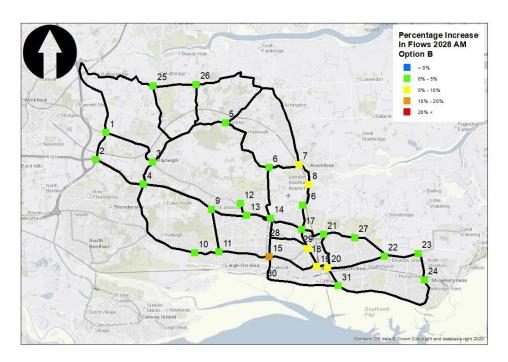

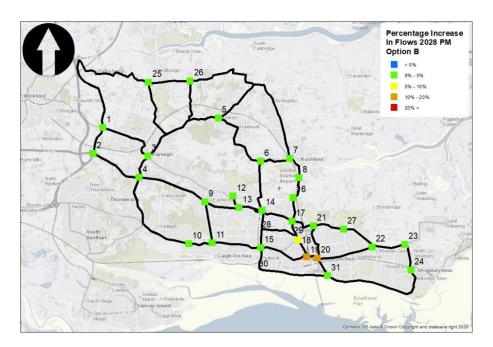

Figure 5.6 Option B 2028 PM

The number of additional dwellings proposed with option B by 2028 only increases by 7% and the results align showing no change for the PM peak, while the AM indicates junctions 7 (Hall Rd / Ashingdon Rd / West St, Rochford) and 8 (Southend Rd / Sutton Rd, Rochford) in Rochford forecast with increases between 5% and 10%.

Figure 5.7 Option B 2038 AM

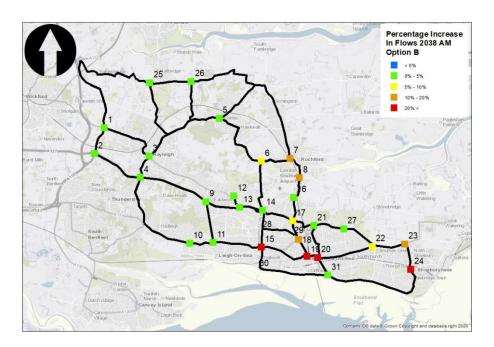

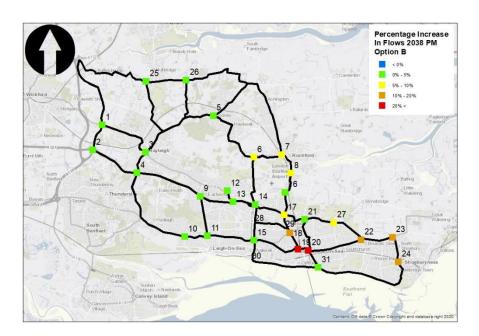

Figure 5.8 Option B 2038 PM

The impact of an additional 30% of dwellings in Option B compared to Option A by 2038 shows further junctions reach the 20% increase of flows threshold in the AM peak, particularly near the loading points for the Central, Prittlewell and Southchurch clusters, which all show significant volumes of additional dwellings. Large volumes of additional dwellings are forecast for Shoeburyness resulting in significant flow increases for junctions 22 (A13 Southchurch Boulevard / Thorpe Hall Ave) to 24 (A13 / Delaware Rd). The flow distributions and DM volumes vary between AM and PM leading to slightly different impacts for junctions 15 (A1158 Westbourne Grove / A13 London Rd) and 22 (A13 Southchurch Boulevard / Thorpe Hall Ave). Junctions 6 (Hall Road / Cherry Orchard Way) to 8 (Southend Rd / Sutton Rd, Rochford) in Rochford are indicated as having flow increases above 5% in both time periods.

Link8	67	71	69	71	11	6	43	23
Link9	1,776	1,862	1,854	1,955	-	4	-	9

The largest increase in flows is forecast at junctions 19 and 20.

5.5 Option C

Option C includes the highest level of potential development growth with an additional 70% of dwellings in 2028 and 60% in 2038 compared to Option B. All of the additional dwellings are proposed at the greenfield sites north of Royal Artillery Way and the North East Southend sites. This is reflected in the results showing between 10% and 20% increases already in 2028 for the eastern end of the A13 and the Royal Artillery Way/Eastern Avenue junction as well as Marine Parade for AM and PM peak.

Figure 5.9 Option C 2028 AM

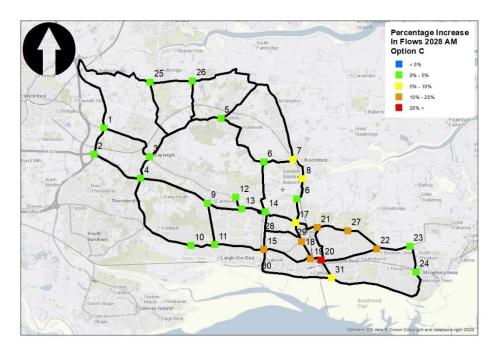

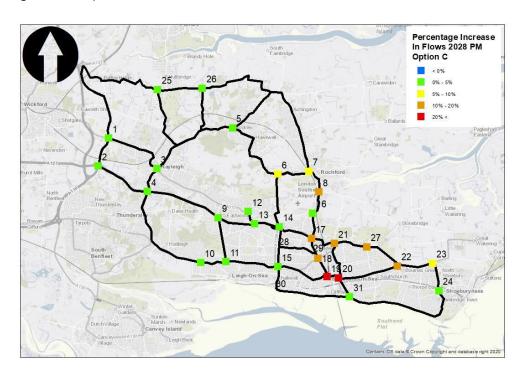

Figure 5.10 Option C 2028 PM

By 2038 the 20% traffic flow growth threshold is reached at most junctions in the centre of Southend, east along the A1159 and the A13. Although junction 16 (Rochford Road/Southend Road/A1159) flow increases remain within the 5% growth level many of the main access points to the Southend Airport are affected by the additional trips from the proposed developments. This could lead to delays accessing the airport location

and consequently have implications for any potential future airport expansion. However, more detailed strategic or junction modelling should be carried out to identify the true impact on journey times and junction operation.

The majority of junctions in Rochford remain between 10% and 20% increase levels, while Junction 31 (Marine Parade/ Eastern Esplanade) also shows increases of this magnitude.

Link8	67	71	69	71	14	16	49	48
Link9	1,776	1,862	1,854	1,955	-	4	-	9

The junctions with the largest flow increases are junctions 19 - 22 and 27 which are located in Southend Central and along the Royal Artillery Way corridor.

5.6 Low Growth

In addition to the options presented above, two sensitivity tests were carried out. The first of these was the low growth scenario, which included a 10% reduction of trips compared to Option A.

This represents the potential equivalent of achieving lower vehicle trip rates due to the promotion of alternative sustainable transport modes, such as public transport or micro-modes through policies or development conditions and travel planning.

Although this is a simplistic representation within the spreadsheet modelling applied and careful consideration to travel planning would be required as part of the proposed dwellings in order to achieve this it indicates at which locations flow level changes reduce into a lower category

Figure 5.13 Low Growth Option 2028 AM

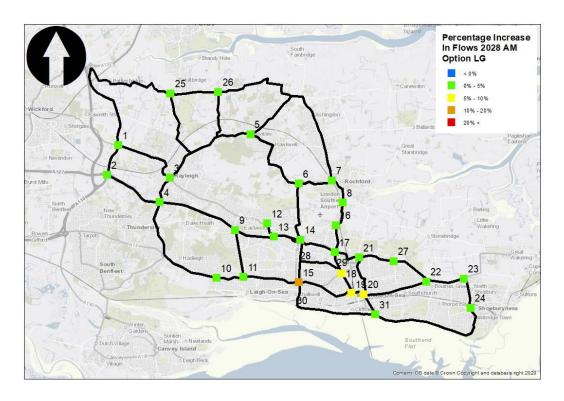

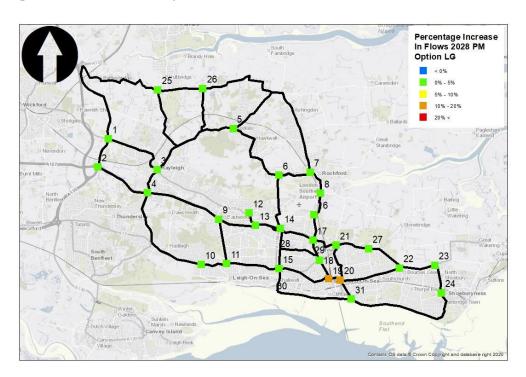

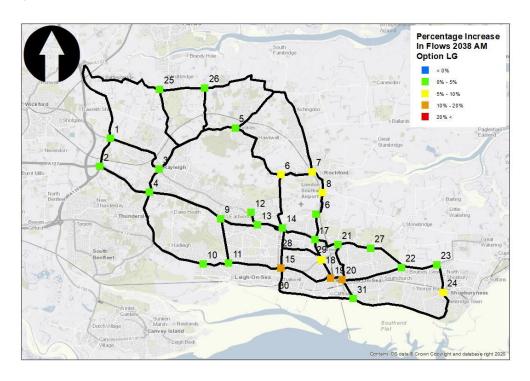

Figure 5.14 Low Growth Option 2028 PM

In 2028 the AM peak low growth option shows the same flow level increase is forecast as for option A. Although overall flow levels reduce, increases compared to the DM are expected at junctions 15, 18, 19 and 20. In the 2028 PM peak low growth option the percentage increase at junction 18 reduces below 5%, which is an improvement compared to Option A.

Figure 5.15 Low Growth Option 2038 AM

The impact of a 10% growth level reduction is more apparent for the 2038 forecasts where Junction 15 (A1158 Westbourne Grove / A13 London Rd), 18 (A127 Victoria Ave/ B1015 Junction, Southend) and 24 (A13 / Delaware Rd / Caulfield Rd / Elm Road) show a lower level of flow increase in the AM peak. While in the PM peak junction 19 (Queensway / Victoria Ave) and 20 (Queensway / A13 Roundabout / A1160) remain above the 10% flow level increase threshold junctions 6 (Hall Road / Cherry Orchard Way) and 7 (Hall Rd /

Ashingdon Rd / West St, Rochford) in Rochford show a lower increase in flow as well as junction 22 (A13 Southchurch Boulevard / Thorpe Hall Ave). None of the junctions show levels of flow increases above 20%.

Link8	67	71	69	71	10	5	25	14
Link9	1,776	1,862	1,854	1,955	-	3	-	6

As in options A and B the junctions with the largest increase in flows are 19 and 20 in central Southend.

5.7 High Growth

The second sensitivity scenario comprises a High Growth scenario. This was requested by SBC to represent further potential greenfield site developments for North East Southend for the Rochford area in addition to Option C. This was set up for 2038, when the majority of these developments would come forward.

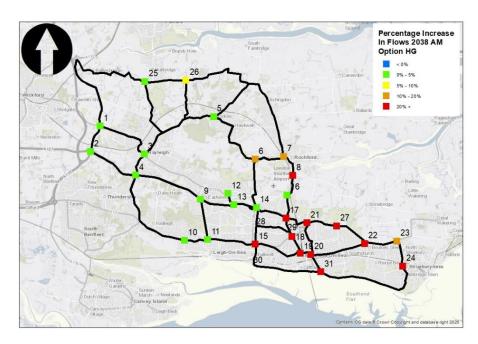

A summary of the dwelling assumptions included in the High Growth scenario are shown below. As the North East Southend cluster is split into three access points for this spreadsheet modelling, as shown in Figure 4.4, the additional dwellings were split equally across the clusters of North East Southend AoS, North of Royal Artillery Way and North of Bournes Green Chase. The increase in dwellings at North East Southend AoS represents a 12% increase overall compared to Option C.

Table 5.7 High Growth dwellings figures

Cluster	Option C Dwellings 2038	High Growth Dwellings 2038	Difference
Eastwood	299	299	0
Leigh	807	807	0
North East Southend AoS	1,859	3,489	1,630
North of Royal Artillery Way	2,440	4,070	1,630
North of Bournes Green Chase	2,962	4,592	1,630
Prittlewell	1,555	1,555	0
Shoeburyness	1,289	1,289	0
Southchurch	1,138	1,138	0
Southend (central)	5,659	5,659	0
Thorpe Bay	90	90	0
Westcliff-on-Sea	834	834	0
Total	18,932	23,822	4,890

The flow increase plots below show that junctions 6 (Hall Road / Cherry Orchard Way) west of Rochford, 17 (A1159 Manners Way - A127 Prince Ave (Cuckoo Corner)) and 31 (Marine Parade / Eastern Esplanade) move into the next flow percentage increase category compared to Option C in the AM peak. This means flow increases are then above 20% for all assessed junctions along Victoria Avenue, Queensway and to the seafront in this peak period.

Figure 5.17 High Growth Option 2038 AM

The PM peak shows flow increases are above 20% for all assessed junctions along Victoria Avenue and Queensway. Flow increases for junctions 2 (Fairglen Interchange), 4 (A129/A127) and 25 (Hullbridge Road / Watery Lane) will move into the 5%-10% category. Due to the majority of developments added in the town centre and the greenfield sites increases above 20% are mainly forecast for central and east Southend areas, with lower percentage increases at the western end of the model.

Figure 5.18 High Growth Option 2038 PM

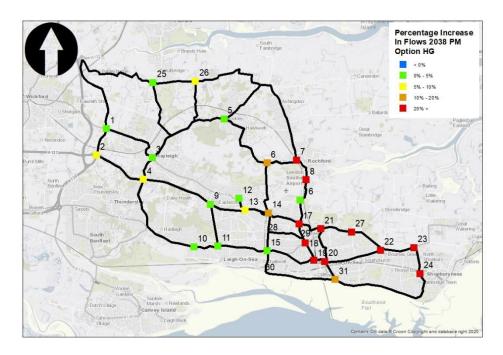

Table 5.8 High Growth Summary Table

Jct/	DM AM Flow	DM PM Flow	DM AM Flow	DM PM Flow	Flow Difference (DS-DM)	Flow Difference (DS-DM)	Flow Difference (DS-DM)	Flow Difference (DS-DM)

Similar to Option C the junctions with the largest increases in flow are junctions 17, 19 - 22 and 27 in Southend Central and along the Royal Artillery Way corridor.

Although the model has not been set up to represent weekend or holiday scenarios the High Growth scenario can also be interpreted to provide a high-level indicator of the impact of increased traffic demand, including for example, that associated with tourism peaks on the seafront junction. Although the leisure trip distribution is likely to be different at the weekend the table above indicates an increase of 400 trips in the AM peak. This is greater than a 20% increase compared to the DM levels. However, peak holiday season traffic levels could be significantly greater than this and a detailed junction assessment should be carried out to identify the impact on the individual turning movements using traffic flows specifically observed during the seasonal peaks.

5.8 Vehicle Kilometres

The spreadsheet model shows the volume of vehicle trip increases which are forecast at key junctions, as described above, but has also been used to estimate the overall distances travelled by vehicles along the network links shown in Table 2.1 associated with the trips calculated in the model. The total distances for 2038 for each option modelled were calculated for Southend and Rochford separately for the AM and PM peaks.

The results in Table 5.9 and Table 5.10 show that the total percentage increases in Option A and B are only marginally greater compared to the DM, however option C levels increase significantly, with the large volume of trips for the AoS loading onto network sections representing NE Southend, Central and Rochford.

It should be noted that the percentages are impacted by the network coverage and would not show comparative results for similar large development further west within Southend with less network coverage.

However, the values below still provide an indication of the impact of each option on the networks and overall vehicle kilometres driven and provide a further high-level indication of the comparative impacts of the development options being considered.

Table 5.9: 2038 AM Vehicle Kilometres

Location	Base	DM	Option A	Option B	Option C	Low Growth	High Growth
Rochford	58,958	67,814	69,363	70,025	70,973	69,208	71,600

5.8.1 PT Journeys

The above analysis is focusing on vehicle trips primarily. In addition, Table 5.11 presents a high-level summary of potential additional total PT trips across Southend based on the total PT trips from each cluster in 2038. The trip calculations followed the same approach as for the vehicle trips but using a more simplistic trip rate approach. The Option values shown in the table only include the additional trips as a result of the potential Local Plan development options (for DM and DS). The same TEMRro growth factor was applied to the DM trips as for the vehicles in order to provide a better comparison of the options.

Table 5.11: Public Transport Trips - Southend 2038

	DM	Option A	Option B	Option C
AM	415	728	840	1,189
РМ	195	361	422	605

6 Summary

In order to help inform the development of the Southend-on-Sea Local Plan a spreadsheet model was set up to help consider the forecast changes in traffic volume for three forecast development options. This report has described the model set-up and assumptions made. The acknowledged limitations of this spreadsheet model are also described below.

6.1 Limitations of the Approach

In the spreadsheet model tool, it was only possible to include a selection of the major highway network junctions and links for areas where suitable junction count information was available. Details about other junctions or links not represented in the model cannot be provided from this tool.

The calculated forecast trip volumes are defined based on consistent assumptions for each development type, size and location only. This is a more simplistic approach than using a strategic modelling tool. However, as trip volume assumptions are made consistently the results enable a quantitative comparison between the options to be made, which is useful at the plan making stage and was agreed in advance with the stakeholders.

The distribution assumptions are established based on a generic set of assumptions about local and longer distance trips and the shortest path route. No consideration about junction delays or re-routing has been made in the spreadsheet model. Therefore, additional trip volumes should not be considered as definitive but indicative only as in reality, driver behaviour may contribute to alternatives such as journey re-routing or trip re-timing. It is therefore recommended that subsequent analysis incorporating this additional level of detail is undertaken in order to help inform considerations of the requirements for improvements for links and junctions which may have capacity issues at a later stage.

Loading points are limited to one or two for each cluster. However, in reality particularly for the larger sized new developments, trips are likely to join the network at different locations. This could lead to overestimation of trips at junctions modelled directly next to a loading point. Again, this should therefore be considered in more detail at a later stage including for example, at the planning application stage when detailed Transport Assessment(s) will be required for each development.

Distributions from and to the Southend and Rochford clusters were used from the BQ model and aligned with the JTW data. However, these showed the majority of trips being short distance trips. Despite some manual adjustments to seek to better account for the trips outside the model area to the west and north, the model is still likely to underrepresent these trips, due to the limited input data.

At this spreadsheet model level, no distinctions between different travel purposes have been made and no conclusions about different travel behaviours can be made differentiating commuting, employers' business or other trips.

Overall, the approach represents an appropriate and agreed high-level analysis for this stage of the plan making process, which was discussed in advance with officers of SBC, RDC and ECC.

6.2 Conclusions

The options tested included an incremental increase in dwellings with Option A including the least additional residential units and employment volumes compared to the DM forecast and Option C including the most.

The analysis showed that there are several junctions forecast with vehicle growth greater than 20% in 2038 even if Option A comes forward within the central areas of Southend. Increases above 5% are located along the A1159 east of A127 and along Southend Road towards Rochford. This aligns with the greater volume of residential units proposed in the Southend central and Prittlewell areas. Despite the urban areas being considered with the lowest trip rates per residential unit due to the proximity to public transport and amenities this housing growth is forecast to generate about 900 additional vehicle trips during the peak hours.

The majority of traffic growth for Option B is mainly forecast for Shoeburyness and Southchurch along the A13 and seafront corridor.

Option C then introduces further growth along the North-East Southend corridor generating additional traffic flows onto the adjacent junctions of greater than 20%.

The low growth sensitivity test has shown that achieving lower levels of vehicle use by providing alternative modes can achieve visibly lower levels of vehicle trips on the road network and less pressure at junctions.

On the contrary, the high growth sensitivity test results in additional volumes of trips on the Southend network if the Rochford greenfield site developments proceed in parallel.

Table 6.1 provides a visual summary of the details provided above. It shows that the majority of junctions see small increases of traffic in percentile terms by 2028. As expected, with the incremental option set up, Option C shows the highest increase with flows at two junctions along Queensway increasing by more than 20%.

By 2038 three junctions are forecast to experience traffic flow increases above 20% even with Option A. This increases to 4 junctions with Option B and 11 junctions with Option C, respectively. Overall these increases are forecast at junctions in the centre of Southend and the eastern sections of Southchurch and Shoeburyness.

Based on the forecast increases at some junctions, it is recommended that more detailed junction modelling is carried out to assess the implications of this growth on the junction capacity. This will vary by junction type, currently available capacity and depend on the distribution of the additional development trips across the approaches.
